What is regression?

In regression we are given a training set in the form of a matrix-vector pair:

$$X = [x_1, \dots, x_m] \in \mathbf{R}^{n \times m}, y \in \mathbf{R}^m$$

where

- ▶ $x_i \in \mathbf{R}^n$ are m data points in n-dimensional "feature space";
- $y = (y_1, \dots, y_m)$ are corresponding "outputs" or "responses".

The goal of regression is to come up with a "prediction rule" $\hat{y}(x)$ that predicts the output for an unseen point $x \in \mathbf{R}^n$.

Linear and non-linear prediction

In linear prediction, we look for prediction rules of the form

$$\hat{y}(x) = w^T x + b$$

where $w \in \mathbf{R}^n$ and $b \in \mathbf{R}$ are the model parameters.

Most methods presented today are directly extended to "non-linear prediction rules", provided we work with non-linear features $\phi(x)$ instead of x, via

$$\hat{\mathbf{y}}(\mathbf{x}) = \mathbf{w}^T \phi(\mathbf{x}) + \mathbf{b}.$$

Example:

$$\hat{y}(x) = w_1 x_1 + w_2 x_2 + w_3 x_1 x_2.$$

In a lecture 7 we explore these ideas in more detail; here we will focus on linear prediction rules.

Model fitting

To fit the model we usually solve a problem such as

$$\min_{w} \mathcal{L}(X^T w + b\mathbf{1}, y) + \lambda p(w),$$

where

- £ is a convex loss function that encodes the error between the observed value and the predicted value;
- \triangleright (w, b) are the model parameters;
- p is a penalty on the regression parameters;
- $\lambda > 0$ is a penalty parameter, obtained via cross-validation.

Most popular models are implemented in open-source packages such as scikit-learn [2].

east-Absolute Deviation

leferences

Validation and testing

The cross-validation (over the penalty parameter λ) involves randomly selecting a subset of the data (representing say 70% of the data points), fitting the model, and testing on the remaining part via the prediction rule.

A new point is then given a predicted output via

$$\hat{y}(x) = w^T x + b.$$

Once that phase is done, we select the best value of the penalty parameter, and provide the final test results on an unseen test set.

Roforoncos

Given $X \in \mathbf{R}^{n \times m}$, $y \in \mathbf{R}^m$, the *Ordinary Least-Squares* (OLS) problem is $\min ||X^T w - y||_2,$

where $\|\cdot\|_2$ denotes the Euclidean norm, and $w \in \mathbf{R}^n$ is the variable.

- Problem is ubiquituous ones in engineering, sciences, economics and finance.
- ▶ Solved by Legendre, Gauss (~ 1850).
- ▶ Very mature solution technology via linear algebra (*e.g.*, SVD) techniques.
- One of the most basic convex problems, used inside many convex optimization algorithms.

Least-squares

Applications

- Fitting auto-regressive models for log-return predictions.
- Various predictions in marketing, consumer credit, econometrics, etc.
- ▶ Solving simple portfolio optimization; index tracking.
- Generally, fitting models to data.

Quantile regression

Interpretation

Smallest distance to consistency

OLS can be interpreted as finding the closest perturbation to "measurement" y to make equation $X^Tw=y$ consistent (meaning, it has a solution w):

$$\min_{w,e} \|e\|_2 : X^T w = y + e.$$

e is noise that corrupted the measurement and made the model inconsistent.

Prediction

Previous interpretation useful in the context of prediction.

- In many cases, each column x_t of data matrix X corresponds to a measurement. (We use t to denote the column index.)
- ► The underlying model is

$$y_t = x_t^T w + e_t, \ t = 1, ..., n,$$

where $e \in \mathbf{R}^T$ is a noise vector. Assume e is random, with $\mathbf{E} e = 0$.

where $e \in \mathbf{R}^T$ is a noise vector. Assume e is random, with $\mathbf{E} e = 0$.

- ▶ Question: if we add one measurement (row x_{n+1}^T of X^T), what will be the corresponding output?
- ▶ *Answer*: since **E** e = 0, the expected value of the new output y_{n+1} is

$$\hat{y}_{n+1} = x_{n+1}^T x.$$

Example

Prediction via auto-regressive models

Auto-regressive (AR) model for time-series y_t :

$$y_t = w_1 y_{t-1} + \ldots + w_p y_{t-p} + e_t, \ t = 1, 2, 3, \ldots$$

where vector $w \in \mathbf{R}^p$ determines the model parameters.

Find x by fitting based on n + p observations of past data $(y_t)_{t=1}^{t=n+p}$

$$\min_{w} ||X^T w - y||_2,$$

where $y=(y_{n+p},\ldots,y_{p+1})$, and $p\times n$ X has t-th column equal to $(y_{n+p-t},\ldots,y_{n+1-t})$.

(Each column of *X* corresponds to a new time point.)

Roforoncos

Once we've solved for w, we can make a prediction based on a new data value y_{n+p+1} :

$$\hat{y}_{n+p+1} = w_1 y_{n+p} + \ldots + w_n y_{n+1}.$$

Allows to form an average prediction error when we run the algorithm in a "sliding window" fashion.

Solution to OLS

If $p \times n$ matrix X is full row rank (XX^T is invertible), solution is unique:

$$w_{\text{OLS}} = (XX^T)^{-1}Xy.$$

- Closed-form expression is rarely used. Algorithms such as QR decomposition or SVD are.
- ▶ Computational complexity grows as $\sim (pn^2 + n^3)$.
- Expression fails when X is not full rank. Then, nullspace of X^T describes ambiguity in solution. SVD methods can provide the whole subspace of solutions.

Overview Regression

Prediction rules
Model fitting

east-squares

Ordinary least-squares

Other Models

LASSO and Elastic Net Least-Absolute Deviation

Regularized least-squares

Definition

In practice, OLS may provide solutions that are very sensitive to changes in input data (A, y).

Regularized LS:

$$\min_{w} \|X^{T}w - y\|_{2}^{2} + \lambda \|w\|_{2}^{2}$$

where $\lambda > 0$ is the *regularization* parameter.

Stochastic interpretation:

$$\min_{w} \mathbf{E} \| (X + N)^T w - y \|_2^2$$

where N is random noise matrix, with $\mathbf{E} N = 0$ and $\mathbf{E} N^T N = \lambda I$.

Regression

Prediction rules

L past-samaro

Ordinary least-squares

Regularized least-squares

eneral model ASSO and Elastic Net ast-Absolute Deviation

leferences

Regularized least-squares

Solution

Solution: always unique, and given by

$$W_{\rm RLS} = (\lambda I + XX^T)^{-1} Xy.$$

- ▶ Parameter $\lambda > 0$ enforces invertibility.
- ▶ This parameter is usually chosen via cross-validation.
- Again, closed-form expression rarely used; linear algebra techniques use OLS method for the equivalent (OLS) problem

$$\min_{w} \left\| \begin{pmatrix} X^T \\ \sqrt{\lambda}I \end{pmatrix} w - \begin{pmatrix} y \\ 0 \end{pmatrix} \right\|_{2}.$$

(Note that matrix involved is always full rank, not matter what data X is.)

Motivation

We will examine different models based on a linear assumption: that, for a new data point $x \in \mathbf{R}^n$, the predicted value is an *affine* function of the input x:

$$\hat{y}(x) = x^T w + b.$$

where $w \in \mathbf{R}^n$ contains the *regression coefficients* and $b \in \mathbf{R}$ is an offset. (In lecture 7, we explore non-linear alternatives.)

Together, w, b are the parameters of the model, which we wish to "learn" from training data samples (x_i, y_i) , $i = 1, \ldots, m$.

Generalized regression

We consider the problem

$$\min_{\mathbf{w}} \mathcal{L}(\mathbf{X}^T \mathbf{w} + b\mathbf{1}, \mathbf{y}) + \lambda p(\mathbf{w}),$$

where

- £ is a convex loss function that encodes the error between the observed value and the predicted value;
- \triangleright (w, b) are the model parameters;
- p is a penalty on the regression parameters;
- $\lambda > 0$ is a penalty parameter.

When $\mathcal{L}(z, y) = ||z - y||_2^2$, $p(w) = ||w||_2^2$, we recover regularized least-squares.

Playing with loss functions and penalties

Changing loss functions allos to cover these types of regression methods:

- Least-absolute deviation: to be less senstive to outliers than LS;
- Quantile regression: to predict intervals of confidence;
- Chebyschev regression: to work with largest errors only;
- KL divergence: to fit probability models

Typical penalties allow to

- I₁-norm: to enforce sparsity;
- I₂-norm (often, squared): to control statistical noise and improve prediction error;
- sum-block norms enable to enforce whole blocks of w to be zero.

east-square

Ordinary least-squares Regularized least-squares

Other Models

General model

east-Absolute Deviation

$$\min_{w} \|X^{T}w - y\|_{2}^{2} + \lambda \|w\|_{1}.$$

- ► Here the model encourages sparsity of the result, due to the term $\|w\|_1$ in the penalty.
- ► The motivation is to be able to *interpret* the results, by finding the features that are most "predictive".
- In practice, we cross-validate the choices of λ. Alternatively: select features first by (pure) LASSO, then run regularized LS. Another alternative is seen next.

LASSO can be unstable (non-unicity of the result), esp. with correlated features.

I ASSO and Flastic Net

LASSO and Elastic Net

Quantile regression

$$\min_{w} \ \|X^T w - y\|_2^2 + \lambda \|w\|_1 + \mu \|w\|_2^2,$$

with $\mu > 0$ an extra regularization parameter.

- ► Here the model still encourages sparsity of the result, due to the term $||w||_1$ in the penalty.
- But it balances the sparsity against some stability.
- And allows for a better control of sparsity.

General m

LASSO and Elastic Net

Quantile regression

In least-absolute deviation, we solve the problem

$$\min_{w} \|X^T w - y\|_1 + \lambda p(w)$$

with (for example) $p(w) = ||w||_2^2$.

- Since the l_1 allows some elements of the vector $X^T w y$ to be large, it can tolerate outliers better than l_2 -norm loss.
- This method is robust, but unstable (it may change much in result to changes in the data).
- Adding a (squared) regularization term p(w) = w^T w allows to control unstability.

Least-Absolute Deviation Quantile regression

Sample quantile

Given values z_1, \ldots, z_m , the *median* is given by

$$\min_{q} \sum_{i=1}^{m} |z_i - q|.$$

More generally, the minimizer for the problem

$$\min_{q} (1 - \tau) \sum_{z_i < q} (q - z_i) + \tau \sum_{z_i \ge q} (z_i - q) = \sum_{i=1}^{n} \rho_{\tau}(z_i - q),$$

gives the $\tau\%$ quantile, with

$$\rho_{\tau}(u) := \max(\tau u, (\tau - 1)u).$$

Finance Data Science 6. Regression

MFE 230P Summer 2017

Quantile regression

Quantile regression

In quantile regression, we solve the problem

$$\min_{\mathbf{w}} \sum_{i=1}^{m} \rho_{\tau}(\mathbf{x}_{i}^{T}\mathbf{w} - \mathbf{y}_{i}) + \lambda p(\mathbf{w})$$

with (for example) $p(w) = ||w||_2^2$.

- A linear or quadratic programming problem.
- Included in the StatsModel package http://www.statsmodels.org/stable/index.html.
